<b>Experiment No.</b>	7

<b>AIM:</b>	Backtracking (N Queens problem )
-------------	----------------------------------

<b>Program 1</b>
------------------

<b>PROBLEM STATEMENT :</b>	To implement N Queens problem using backtrack
----------------------------	---

<b>ALGORITHM:</b>	<ol style="list-style-type: none"> <li>Initialize an empty chessboard of size NxN.</li> <li>Start with the leftmost column and place a queen in the first row of that column.</li> <li>Move to the next column and place a queen in the first row of that column.</li> <li>Repeat step 3 until either all N queens have been placed or it is impossible to place a queen in the current column without violating the rules of the problem.</li> <li>If all N queens have been placed, print the solution.</li> <li>If it is not possible to place a queen in the current column without violating the rules of the problem, backtrack to the previous column.</li> <li>Remove the queen from the previous column and move it down one row.</li> <li>Repeat steps 4-7 until all possible configurations have been tried.</li> </ol>
-------------------	--

<b>PROGRAM:</b>	<pre>#include&lt;stdio.h&gt; #include&lt;math.h&gt;  int board[20],count;  int main() { int n,i,j; void queen(int row,int n);  printf(" - N Queens Problem Using Backtracking -"); printf("\n\nEnter number of Queens:");</pre>
-----------------	---

```

scanf("%d",&n);
queen(1,n);
return 0;
}

//function for printing the solution
void print(int n)
{
int i,j;
printf("\n\nSolution %d:\n\n",++count);

for(i=1;i<=n;++i)
    printf("\t%d",i);

for(i=1;i<=n;++i)
{
    printf("\n%d",i);
    for(j=1;j<=n;++j) //for nxn board
    {
        if(board[i]==j)
            printf("\tQ"); //queen at i,j position
        else
            printf("\t-"); //empty slot
    }
}
}

/*funtion to check conflicts
If no conflict for desired postion returns 1 otherwise returns 0*/
int place(int row,int column)
{
int i;
for(i=1;i<=row-1;++i)
{
    //checking column and digonal conflicts
    if(board[i]==column)
        return 0;
    else
        if(abs(board[i]-column)==abs(i-row))
            return 0;
}
}

```

	<pre> }  return 1; //no conflicts }  //function to check for proper positioning of queen void queen(int row,int n) { int column; for(column=1;column&lt;=n;++column) { if(place(row,column)) { board[row]=column; //no conflicts so place queen if(row==n) //dead end print(n); //printing the board configuration else //try queen with next position queen(row+1,n); } } } </pre>
<b>OBSERVATION:</b>	<p><b>Complexity Analysis</b></p> <ul style="list-style-type: none"> <li>Time complexity: <math>O(N!)</math>: The first queen has <math>N</math> placements, the second queen must not be in the same column as the first as well as at an oblique angle, so the second queen has <math>N-1</math> possibilities, and so on, with a time complexity of <math>O(N!)</math>.</li> <li>Spatial Complexity: <math>O(N)</math>: Need to use arrays to save information.</li> </ul>

## RESULT:

```
Enter number of Queens:4
```

```
Solution 1:
```

	1	2	3	4
1	-	Q	-	-
2	-	-	-	Q
3	Q	-	-	-
4	-	-	Q	-

```
Solution 2:
```

	1	2	3	4
1	-	-	Q	-
2	Q	-	-	-
3	-	-	-	Q
4	-	Q	-	-

```
...Program finished with exit code 0  
Press ENTER to exit console.
```

## CONCLUSION:

In this experiment, we implemented N queens problem using backtracking.
